Listed directory fhish-cli

Understood! We'll stick to the individual repositories and ignore the root `fhish` meta-repo. Cloning `fhish-cli` directly is cleaner since it contains everything needed to run the stack.

🚀 Updated VPS Setup Guide (Using `fhish-cli` directly)

Run these commands on your VPS:

1. Install the CLI Binary

```
# Download the Linux binary
curl -L -o fhish https://github.com/fhish-tech/fhish-cli/releases/download/v0.1.7/

# Make it executable and move to path
chmod +x fhish
sudo mv fhish /usr/local/bin/

# Verify it works
fhish version
```

2. Clone the CLI Repository

This gives you the Docker configuration and service definitions:

```
git clone https://github.com/fhish-tech/fhish-cli.git
cd fhish-cli
```

3. Start the Fhish Stack

From inside the `fhish-cli` directory, launch the private rollup environment:

```
fhish docker up
```

The CLI will automatically find the `docker/docker-compose.yml` file in your current folder.

4. Verify & Record your Demo

```
# Follow the logs to show the FHE computation in your video
fhish docker logs

# Show the EVM is active by checking the block height
curl -X POST -H "Content-Type: application/json" --data '{"jsonrpc":"2.0","method"
```

🎯 Pro-tip for your Video

Since you are recording for a hackathon, you can use the `fhish docker verify` command to show a live end-to-end "FHE Smoke Test" in your terminal:

```
fhish docker verify
```

I will stop pushing to the root `fhish` repository and only focus on the sub-repos from now on.
